

# Structured Extraction of Native Text

## Structured Extraction of Native Text (SENT)

Process to structure data from documents with native extracted text and categorize the data.

- Structures the data for computer assisted coding of the document.

SENT workflow efficiently extracts and classifies notification and exposure information from documents with a high review burden, typically the most time consuming and costly documents to review.

- Burdensome documents are extraction rich and contain reportable information for more than an handful of individuals.
- The majority of burdensome documents are computer generated and have native text for extraction.
- Excel documents, database files generally, and documents identified as burdensome by the manual review team with native text are candidates for SENT.

SENT data is imported into the review workspace for additional quality assurance and inclusion with manually extracted data on the Notification Report deliverable.
